## Research Objective, ADAM-project

- To assess, how EU mitigation and adaptation policies can achieve a transition to a world with a global climate no warmer than 2°C above pre-industrial levels, and to identify their associated costs and effectiveness.
- The analysis of adaptation technologies including their cost and impact
- Scenario-development in the framework of the European ADAM-project
  - Special focus on influence of climate change on the European electricity sector

# ADAM M1-project setup

Technology mix, emissions, investments on new technologies in the energy conversion sector for EU-29

- 
- 1 Research Objective
  - 2 Methodology
  - 3 Scenario Analysis
    - Base scenario
    - Adaptation scenario
    - Mitigation Scenario, preliminary
  - 4 Conclusion

---

## Model description, EuroMM

- MARKAL-class model
- "bottom-up" energy-system model with detailed representation of technologies
- cost-optimization model: identifies least-cost solutions for the energy system under given sets of assumptions and constraints
- represents the energy system of EU-29

---

## EuroMM features

- Detailed representation of electricity and heat production
- 18 aggregated European regions for EU-29
- Bilateral trade of electricity between regions
- 3 level electricity grid
- Trade, production and conversion of primary energy carriers

## Reference energy system

Each Technology is represented by its costs and efficiency!

- 
- 1 Research Objective
  - 2 Methodology
  - 3 Scenario Analysis
    - Base scenario
    - Adaptation scenario
    - Mitigation Scenario, preliminary
  - 4 Conclusion

## Base scenario, assumptions

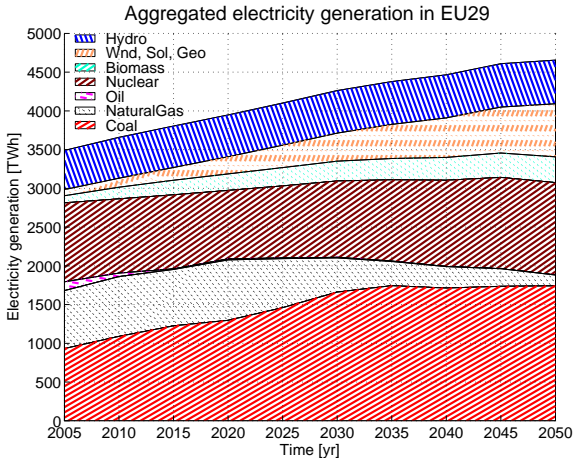

- Business as usual
- Low  $CO_2$ -tax (10 US\$/t $CO_2$ )
- No impacts of climate change on electricity sector assumed

# Primary energy demand, base scenario

# Electricity generation, base scenario

- 
- 1 Research Objective
  - 2 Methodology
  - 3 Scenario Analysis
    - Base scenario
    - **Adaptation scenario**
    - Mitigation Scenario, preliminary
  - 4 Conclusion

---

## Adaptation scenario, assumptions

- Changes in energy demands and renewable power generation
- Low  $CO_2$ -tax (10  $US\$ \backslash tCO_2$ )
- Climate change: temperature  $+2^\circ C$  in 2050  
→ **lower power-plant efficiency and availability**

## Modeling the impacts of climate change

- Submodule to estimate effects of climate change on cooling capacity of rivers
  - Threshold of 25°C in water temperature which allows for use in cooling
- lower availability, if threshold is reached
- Reduced power plant efficiency for ideal Rankine cycle (0.1% efficiency reduction per 1°C higher cooling water temperature, [Durmazyan A. & Sogut O.S., 2006.] )

# Technology options for adaptation of electricity generation<sup>1</sup>

- Installation of wet cooling tower
- Installation of dry cooling tower

Cooling system	Additional INVcost [US\$/kW]	water demand [m <sup>3</sup> /MWh]	FIXOM [US\$/kW]	Losses [%]
Wet cooling tower	6 - 8	0.95	0.7	-
Dry cooling tower	40 - 100	0.038	-	0.2-1%

- Analysis of influence of temperature change on power plant efficiency and availability

<sup>1</sup>  
[CEC, 2002]

# Aggregated electricity generation for EU-29

# Comparison for Italy between base and reference case

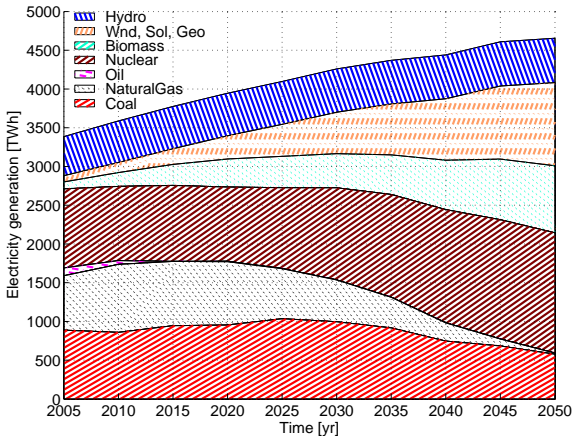

- 
- 1 Research Objective
  - 2 Methodology
  - 3 Scenario Analysis
    - Base scenario
    - Adaptation scenario
    - Mitigation Scenario, preliminary
  - 4 Conclusion

---

## Assumptions mitigation scenario

- Identical demands as in Base Scenario
- Increasing  $CO_2$ -tax, up to 50 US\$ /  $tCO_2$  in 2050 (according to POLES 550ppm-scenario)
- EU29 biomass potential of 7.2EJ/year
- 4.7EJ wind power potential (World Energy Assessment, 2000)

# Electricity generation, mitigation case

- 
- 1 Research Objective
  - 2 Methodology
  - 3 Scenario Analysis
    - Base scenario
    - Adaptation scenario
    - Mitigation Scenario, preliminary
  - 4 Conclusion

---

## Conclusions

- Adaptation scenarios are important to depict critical states for electricity production
- Adaptation requires some important changes in the electricity sector
- Shift of peak electricity demand from winter to summer
- Electricity sector can only contribute to 30% of emission reduction in a mitigation scenario

---

## Further research

- Seasonal variability of electricity demand and generation should be included
- Update of the demand side for mitigation case
- Including solar electricity generation in Africa

---

**Thank you for your attention**
